For centuries, scientists have debated the origin of humans. Some have argued that we evolved from apes, while others have suggested that we were created by a higher power. However, new DNA research has shed new light on this mystery, and the results are astonishing.

The Human Genome Project, which was completed in 2003, sequenced the entire human genome. This massive undertaking provided scientists with a wealth of new information about our DNA, and it has led to a number of important discoveries.

One of the most important discoveries is that humans are not as closely related to apes as we once thought. In fact, we are more closely related to chimpanzees than we are to gorillas or orangutans.

This finding has led scientists to revise their theories about human evolution. They now believe that humans and chimpanzees diverged from a common ancestor about 6 million years ago. This is much earlier than the previous estimate of 2 million years ago.

Another important discovery is that humans have a much more complex genetic makeup than we once thought. The human genome contains over 3 billion base pairs of DNA, and only about 2% of these base pairs code for proteins.

The remaining 98% of our DNA is composed of non-coding DNA, which was once thought to be junk DNA. However, scientists are now learning that non-coding DNA plays an important role in regulating gene expression.

These new discoveries are providing scientists with a new understanding of human evolution. They are also leading to new insights into human diseases and conditions.

The True Origin Story Revealed By DNA New Research is a groundbreaking book that presents the latest evidence about human evolution. This book is a must-read for anyone who is interested in the origin of our species.
